

# Package ‘quadrupen’

June 5, 2026

**Type** Package

**Title** Sparse and Group Sparse Linear Models

**Version** 1.0-0

**Date** 2026-06-05

**Description** Fits the solution paths of classical sparse regression models with efficient active set algorithms by solving small sub-problems. Include LASSO, SCAD, MCP, (Sparse) Group-LASSO, Cooperative-LASSO, (Group) LAVA, (Generalized) Fused-Lasso and (Generalized) Elastic-Net. Also provides methods for model selection purpose (information criteria, cross-validation, stability selection).

**URL** <https://github.com/jchiquet/quadrupen>,  
<https://jchiquet.github.io/quadrupen/>

**BugReports** <https://github.com/jchiquet/quadrupen/issues>

**License** GPL (>= 3)

**Encoding** UTF-8

**Language** en-US

**SystemRequirements** GNU make

**Depends** R (>= 4.1.0)

**Imports** dplyr, ggplot2, grid, Matrix, methods, parallel, R6, Rcpp, rlang, scales, tidyr, lifecycle

**Suggests** elasticnet, glmnet, igraph, knitr, lars, MASS, ncvreg, gpreg, rmarkdown, testthat

**LinkingTo** Rcpp, RcppArmadillo

**Collate** 'init.R' 'quadrupen-package.R' 'QuadrupenFit-R6Class.R'  
'quadrupen-S3Methods.R' 'Regularizers-R6Class.R'

BoundedRegressionFit    *Class "BoundedRegression"*

---

## Description

Class of object returned by the fitting function [bounded\\_reg\(\)](#). Inherits fields and methods of [QuadrupenFit](#).

## Super class

[QuadrupenFit](#) -> BoundedRegressionFit

## Active bindings

penalty    character describing the regularizer/penalty  
lambda1nf    vector of tuning parameters for the l1nf penalty  
lambda2    vector of tuning parameters for the l2 penalty

## Methods

### Public methods:

- [BoundedRegressionFit\\$new\(\)](#)
- [BoundedRegressionFit\\$clone\(\)](#)

[BoundedRegressionFit\\$new\(\)](#): Initialize a [BoundedRegressionFit](#) model

*Usage:*

[BoundedRegressionFit\\$new](#)(data, intercept, regParam)

*Arguments:*

data    a [DataModel](#) object

intercept    a logical; should an intercept be included in the mode?

regParam    a list with two elements, a vector and a scalar, for the regularization

[BoundedRegressionFit\\$clone\(\)](#): The objects of this class are cloneable with this method.

*Usage:*

[BoundedRegressionFit\\$clone](#)(deep = FALSE)

*Arguments:*

deep    Whether to make a deep clone.

## See Also

[QuadrupenFit](#), [bounded\\_reg\(\)](#)

---

bounded\_reg

*Fit a linear model with infinity-norm plus ridge-like regularization*

---

### Description

Adjust a linear model penalized by a (possibly weighted)  $\ell_\infty$ -norm (bounding the magnitude of the parameters) and a (possibly structured)  $\ell_2$ -norm (ridge-like). The solution path is computed at a grid of values for the infinity-penalty, fixing the amount of  $\ell_2$  regularization. See details for the criterion optimized.

### Usage

```
bounded_reg(
  x,
  y,
  lambda1 = NULL,
  lambda2 = 0.01,
  penscale = rep(1, ncol(x)),
  struct = Matrix::Diagonal(ncol(x), 1),
  intercept = TRUE,
  normalize = TRUE,
  nlambda1 = ifelse(is.null(lambda1), 100, length(lambda1)),
  minratio = ifelse(nrow(x) <= ncol(x), 0.01, 1e-04),
  maxfeat = ifelse(lambda2 < 0.01, min(nrow(x), ncol(x)), min(4 * nrow(x), ncol(x))),
  control = list()
)
```

```
bounded.reg(
  x,
  y,
  lambda1 = NULL,
  lambda2 = 0.01,
  penscale = rep(1, ncol(x)),
  struct = Matrix::Diagonal(ncol(x), 1),
  intercept = TRUE,
  normalize = TRUE,
  nlambda1 = ifelse(is.null(lambda1), 100, length(lambda1)),
  minratio = ifelse(nrow(x) <= ncol(x), 0.01, 1e-04),
  maxfeat = ifelse(lambda2 < 0.01, min(nrow(x), ncol(x)), min(4 * nrow(x), ncol(x))),
  control = list()
)
```

### Arguments

x matrix of features, possibly sparsely encoded (experimental). Do NOT include intercept. When normalized is TRUE, coefficients will then be rescaled to the original scale.

y	response vector.
lambda1	sequence of decreasing $\ell_1$ -penalty levels. If NULL (the default), a vector is generated with nlambda1 entries, starting from a guessed level lambda1.max where only the intercept is included, then shrunken to minratio*lambda1.max.
lambda2	real scalar; tunes the $\ell_2$ penalty in the Elastic-net. Default is 0.01. Set to 0 to recover the Lasso.
penscale	vector with real positive values that weight the penalty of each feature. Default sets all weights to 1.
struct	matrix structuring the coefficients, possibly sparsely encoded. Must be at least positive semidefinite (this is checked internally). If NULL (the default), the identity matrix is used. See details below.
intercept	logical; indicates if an intercept should be included in the model. Default is TRUE.
normalize	logical; indicates if variables should be normalized to have unit L2 norm before fitting. Default is TRUE.
nlambda1	integer that indicates the number of values to put in the lambda1 vector. Ignored if lambda1 is provided.
minratio	minimal value of $\ell_1$ -part of the penalty that will be tried, as a fraction of the maximal lambda1 value. A too small value might lead to instability at the end of the solution path corresponding to small lambda1 combined with $\lambda_2 = 0$ . The default value tries to avoid this, adapting to the ' $n < p$ ' context. Ignored if lambda1 is provided.
maxfeat	integer; limits the number of features ever to enter the model; i.e., non-zero coefficients for the Elastic-net: the algorithm stops if this number is exceeded and lambda1 is cut at the corresponding level. Default is $\min(\text{nrow}(x), \text{ncol}(x))$ for small lambda2 ( $< 0.01$ ) and $\min(4 * \text{nrow}(x), \text{ncol}(x))$ otherwise. Use with care, as it considerably changes the computation time.
control	list of argument controlling low level options of the algorithm –use with care and at your own risk– : <ul style="list-style-type: none"> <li>• verbose: integer; activate verbose mode –this one is not too risky!– set to 0 for no output; 1 for warnings only, and 2 for tracing the whole progression. Default is 1. Automatically set to 0 when the method is embedded within cross-validation or stability selection.</li> <li>• timer: logical; use to record the timing of the algorithm. Default is FALSE.</li> <li>• maxiter the maximal number of iteration used in the active set algorithm to solve the problem for a given value of lambda1 . Default is 50.</li> <li>• method a string for the underlying solver used. Either "quadra", "fista" or "pgd". Default is "quadra".</li> <li>• factmat Boolean indicating if matrix factorization should be used to solve the sub-system. If TRUE (the default), a Cholesky decomposition is maintained along the path. If FALSE, the sub-system are solved with a conjugate gradient algorithm.</li> <li>• threshold a threshold for convergence. The algorithm stops when the optimality conditions are fulfill up to this threshold. Default is <math>1e-6</math>.</li> </ul>

- monitor indicates if a monitoring of the convergence should be recorded, by computing a lower bound between the current solution and the optimum: when '0' (the default), no monitoring is provided; when '1', the bound derived in Grandvalet et al. is computed; when '>1', the Fenchel duality gap is computed along the algorithm.

## Details

The optimized criterion is the following:

$$\hat{\beta}_{\lambda_1, \lambda_2} = \arg \min_{\beta} \frac{1}{2} (y - X\beta)^T (y - X\beta) + \lambda_1 \|D\beta\|_{\infty} + \frac{\lambda_2}{2} \beta^T S \beta,$$

where  $D$  is a diagonal matrix, whose diagonal terms are provided as a vector by the penscale argument. The  $\ell_2$  structuring matrix  $S$  is provided via the struct argument, a positive semidefinite matrix (possibly of class Matrix).

Note that the quadratic algorithm for the bounded regression may become unstable along the path because of singularity of the underlying problem, e.g. when there are too much correlation or when the size of the problem is close to or smaller than the sample size. In such cases, it might be a good idea to switch to the proximal solver, slower yet more robust. This is the strategy automatically adopted in code, that will send a warning in verbose mode while switching the method to 'fista' and keep on optimizing on the remainder of the path.

Singularity of the system can also be avoided with a larger  $\ell_2$ -regularization, via lambda2, or a "not-too-small"  $\ell_{\infty}$  regularization, via a larger 'minratio' argument.

## Value

an object with class `QuadrupenFit`.

an object with class `BoundedRegressionFit`, inheriting from `QuadrupenFit`.

## Examples

```
## Simulating multivariate Gaussian with blockwise correlation
## and piecewise constant vector of parameters
beta <- rep(c(0,1,0,-1,0), c(25,10,25,10,25))
cor <- 0.75
Soo <- toeplitz(cor^(0:(25-1))) ## Toeplitz correlation for irrelevant variables
Sww <- matrix(cor,10,10) ## bloc correlation between active variables
Sigma <- Matrix::bdiag(Soo,Sww,Soo,Sww,Soo)
diag(Sigma) <- 1
n <- 50
x <- as.matrix(matrix(rnorm(95*n),n,95) %%% chol(Sigma))
y <- 10 + x %%% beta + rnorm(n,0,10)

## Infinity norm without/with an additional l2 regularization term
## and with structuring prior
labels <- rep("irrelevant", length(beta))
labels[beta != 0] <- "relevant"
plot(bounded_reg(x,y,lambda2=0), label=labels) ## a mess
plot(bounded_reg(x,y,lambda2=10), label=labels) ## good guys are at the boundaries
```

```
plot(bounded_reg(x,y,lambda2=10,struct=solve(Sigma)), label=labels) ## even better
```

---

```
coef.QuadrupenFit      Extract model coefficients
```

---

### Description

Extracts model coefficients from a [QuadrupenFit](#) object

### Usage

```
## S3 method for class 'QuadrupenFit'
coef(object, selection = NULL, ...)
```

### Arguments

object	a <a href="#">QuadrupenFit</a> object
selection	either a character (model selection criteria) of a scalar (lambda value)
...	not used, only here for S3 compatibility

### Value

a vector of coefficients

---

```
criteria      Penalized criteria based on estimation of degrees of freedom
```

---

### Description

Produce a plot or send back the values of some penalized criteria accompanied with the vector(s) of parameters selected accordingly. The default behavior plots the BIC and the AIC (with respective factor  $\log(n)$  and 2) yet the user can specify any penalty.

### Usage

```
criteria(
  object,
  penalty = setNames(c(2, log(object$nobs), log(object$nvar), log(object$nobs) + 2 *
    log(object$nvar)), c("AIC", "BIC", "mBIC", "eBIC")),
  sigma = NULL
)

## S3 method for class 'QuadrupenFit'
criteria(
```

```

object,
penalty = setNames(c(2, log(object$nobs), log(object$nvar), log(object$nobs) + 2 *
  log(object$nvar)), c("AIC", "BIC", "mBIC", "eBIC")),
sigma = NULL
)

```

### Arguments

object	output of a fitting procedure of the <b>quadrupen</b> package (e.g. <code>elastic_net()</code> ).
penalty	a vector with as many penalties a desired. The default contains the penalty corresponding to the AIC and the BIC (2 and $\log(n)$ ). Setting the "names" attribute, as done in the default definition, leads to outputs which are easier to read.
sigma	scalar: an estimate of the residual variance. When available, it is plugged-in the criteria, which may be more relevant. If NULL (the default), it is estimated as usual (see details).

### Value

an object with class `InformationCriteria` is sent back and stored as a field of the original `QuadrupenFit` object.

### Methods (by class)

- `criteria(QuadrupenFit)`: S3 method for information criteria of a `QuadrupenFit`

### Note

When sigma is provided, the criterion takes the form

$$\left\| \mathbf{y} - \mathbf{X}\hat{\beta} \right\|^2 + \text{penalty} \times \frac{\hat{\text{df}}}{n} \sigma^2.$$

When it is unknown, it writes

$$\log \left( \left\| \mathbf{y} - \mathbf{X}\hat{\beta} \right\|^2 \right) + \text{penalty} \times \hat{\text{df}}.$$

Estimation of the degrees of freedom (for the elastic-net, the LASSO and also bounded regression) are computed by applying and adapting the results of Tibshirani and Taylor (see references below).

### References

**Examples**

```
## Not run:
## Simulating multivariate Gaussian with blockwise correlation
## and piecewise constant vector of parameters
beta <- rep(c(0,1,0,-1,0), c(25,10,25,10,25))
cor <- 0.75
Soo <- toeplitz(cor^(0:(25-1))) ## Toeplitz correlation for irrelevant variables
Sww <- matrix(cor,10,10) ## bloc correlation between active variables
Sigma <- bdiag(Soo,Sww,Soo,Sww,Soo)
diag(Sigma) <- 1
n <- 50
x <- as.matrix(matrix(rnorm(95*n),n,95) %%% chol(Sigma))
y <- 10 + x %%% beta + rnorm(n,0,10)

## Plot penalized criteria for the Elastic-net path
criteria(elastic_net(x,y, lambda2=1))

#' Plot penalized criteria for the Bounded regression
criteria(bounded_reg(x,y, lambda2=1))

## End(Not run)
```

---

CrossValidation

*Class CrossValidation*

---

**Description**

Class of object returned by the `QuadrupenFit$cross_validate()` method or the `cross_validate()` function. Owns `print()` and `plot()` methods.

**Active bindings**

`data` a data frame containing the mean cross-validated error and its associated standard error for each values of `lambda1` and `lambda2`.

`folds` list of  $K$  vectors indicating the folds used for cross-validation.

`lambda1` vector of  $\lambda_1$  ( $\ell_1$  or  $\ell_\infty$  penalty levels) for which each cross-validation has been performed.

`lambda2` vector (or scalar) of  $\ell_2$ -penalty levels for which each cross-validation has been performed.

`lambda1_min` level of  $\lambda_1$  that minimizes the error estimated by cross-validation.

`lambda2_min` level of  $\lambda_2$  that minimizes the error estimated by cross-validation.

`lambda1_1se` largest level of  $\lambda_1$  such as the cross-validated error is within 1 standard error of the minimum.

`lambda2_1se` largest level of  $\lambda_2$  such that the cross-validated error is within 1 standard error of the minimum (only relevant for ridge regression).

**Methods****Public methods:**

- `CrossValidation$new()`
- `CrossValidation$show()`
- `CrossValidation$print()`
- `CrossValidation$plotCV_1D()`
- `CrossValidation$plotCV_2D()`
- `CrossValidation$plot()`
- `CrossValidation$clone()`

`CrossValidation$new()`: Constructor for a `CrossValidation` object Should be called internally by an object `QuadrupenFit$cross_validate()`

*Usage:*

```
CrossValidation$new(cv_error, folds)
```

*Arguments:*

`cv_error` data frame storing output of a cv job  
`folds` list of K folds used for cross-validation

`CrossValidation$show()`: User friendly print method

*Usage:*

```
CrossValidation$show()
```

`CrossValidation$print()`: User friendly print method

*Usage:*

```
CrossValidation$print()
```

`CrossValidation$plotCV_1D()`: Plot 1-dimensional cross-validation

*Usage:*

```
CrossValidation$plotCV_1D(  
  log_scale = TRUE,  
  title = "Cross-validation error",  
  se = TRUE  
)
```

*Arguments:*

`log_scale` logical, should a log-scale be used for the x-axis  
`title` graph title  
`se` logical, should confidence band be displayed (TRUE by default)

*Returns:* a ggplot object

`CrossValidation$plotCV_2D()`: Plot 2-dimensional cross-validation output (grid `lambda1` x `lambda2`)

*Usage:*

```
CrossValidation$plotCV_2D(title = "Cross-validation error")
```

*Arguments:*

title graph title

*Returns:* a **ggplot2** object

CrossValidation\$plot(): Plot cross-validation job by choosing the most appropriate output (1D- or 2D)

*Usage:*

CrossValidation\$plot(log\_scale = TRUE, title = "Cross-validation error")

*Arguments:*

log\_scale logical, should a log-scale be used for the x-axis

title graph title

*Returns:* a ggplot object

CrossValidation\$clone(): The objects of this class are cloneable with this method.

*Usage:*

CrossValidation\$clone(deep = FALSE)

*Arguments:*

deep Whether to make a deep clone.

---

 cross\_validate

---

*Cross-validation for Quadrupen object*

---

**Description**

Function that computes K-fold cross-validated error of a quadrupen fit, possibly on a grid of lambda1, lambda2.

**Usage**

```
cross_validate(
  object,
  K = 10,
  folds = split(sample(1:object$nobs), rep(1:K, length = object$nobs)),
  lambda2 = object$minor_tuning,
  verbose = TRUE,
  cores = 1
)
```

```
## S3 method for class 'QuadrupenFit'
```

```
cross_validate(
  object,
  K = 10,
  folds = split(sample(1:object$nobs), rep(1:K, length = object$nobs)),
  lambda2 = object$minor_tuning,
  verbose = TRUE,
  cores = parallel::detectCores() - 2
)
```

**Arguments**

object	an R6 object with class <a href="#">QuadrupenFit</a>
K	integer indicating the number of folds. Default is 10.
folds	list of K vectors that describes the folds to use for the cross-validation. By default, the folds are randomly sampled with the specified K. The same folds are used for each values of lambda2.
lambda2	tunes the $\ell_2$ -penalty (ridge-like) of the fit. If none is provided, a vector of values is generated and a CV is performed on a grid of lambda2 and lambda1, using the same folds for each lambda2.
verbose	logical; indicates if the progression (the current lambda2 should be displayed. Default is TRUE.
cores	the number of cores to use. The default uses 1 core (safer in case your BLAS/LAPACK libraries are multithreaded)

**Value**

an object with class [CrossValidation](#) is sent back and stored as a field of the original [QuadrupenFit](#) object.

**Methods (by class)**

- `cross_validate(QuadrupenFit)`: S3 method for cross-validation of a [QuadrupenFit](#)

**Note**

If the user runs the fitting method with option 'bulletproof' set to FALSE, the algorithm may stop at an early stage of the path. Early stops are handled internally, in order to provide results on the same grid of penalty tuned by  $\lambda_1$ . This is done by means of NA values, so as mean and standard error are consistently evaluated. If, while cross-validating, the procedure experiences too much early stops, a warning is sent to the user, in which case you should reconsider the grid of lambda1 used for the cross-validation. If bulletproof is TRUE (the default), there is nothing to worry about, except a possible slow down when any switching to the proximal algorithm is required.

**Examples**

```
## Not run:
## Simulating multivariate Gaussian with blockwise correlation
## and piecewise constant vector of parameters
beta <- rep(c(0,1,0,-1,0), c(25,10,25,10,25))
cor <- 0.75
Soo <- toeplitz(cor^(0:(25-1))) ## Toeplitz correlation for irrelevant variable
Sww <- matrix(cor,10,10) ## bloc correlation between active variables
Sigma <- bdiag(Soo,Sww,Soo,Sww,Soo) + 0.1
diag(Sigma) <- 1
n <- 100
x <- as.matrix(matrix(rnorm(95*n),n,95) %%% chol(Sigma))
y <- 10 + x %%% beta + rnorm(n,0,10)
```

```

enet <- elastic_net(x, y, nlambda1=50)

## Use fewer lambda1 values by overwriting the default parameters
## and cross-validate over the sequences lambda1 and lambda2
cv.grid <- cross_validate(enet, lambda2=10^seq(2,-2,len=50))
## Rerun simple cross-validation with the appropriate lambda2
cv.10K <- crossval(x,y, lambda2=cv.grid$lambda2_min)
## Try leave one out also
cv.loo <- crossval(x,y, K=n, lambda2=cv.grid$lambda2_min)

plot(cv.grid)
plot(cv.10K)
plot(cv.loo)

## Performance for selection purpose
cat("\nFalse positives with the minimal 10-CV choice: ", sum(sign(beta) != sign(cv.10K$beta_min )))
cat("\nFalse positives with the minimal L00-CV choice: ", sum(sign(beta) != sign(cv.loo$beta_min)))

## End(Not run)

```

---

DataModel

*Data Class*

---

### Description

Class for storing data and various fixed quantity

### Public fields

X matrix of regressor  
y vector of response  
C\_inv Inverse of the Cholesky decomposition of S  
S SDP structuring matrix  
wy vector of observation weights

### Active bindings

d number of regressor  
n sample size  
sparse\_encoding logical indicating if the matrix of regressor is sparsely encoded  
varnames character, the names of the covariates/regressors  
normx norm of each column of X

## Methods

### Public methods:

- `DataModel$new()`
- `DataModel$CholStruct()`
- `DataModel$splitTrainTest()`
- `DataModel$splitSubSamples()`
- `DataModel$clone()`

`DataModel$new()`: constructor for DataModel

*Usage:*

```
DataModel$new(
  covariates,
  outcome,
  cov_struct,
  obs_weights = rep(1, length(outcome)),
  check_args = TRUE
)
```

*Arguments:*

`covariates` matrix of covariates/regressors  
`outcome` vector of outcome/response  
`cov_struct` sdv matrix structuring the covariates/regressors  
`obs_weights` vector of observations weights  
`check_args` logical, should args be check at initialization?  
`cov_weights` vector of covariates/regressors weights

`DataModel$CholStruct()`: Compute Cholesky factorization of the Structuring matrix

*Usage:*

```
DataModel$CholStruct()
```

`DataModel$splitTrainTest()`: a function splitting the data into train and test folds

*Usage:*

```
DataModel$splitTrainTest(
  nfolds = 10,
  folds = split(sample(1:self$n), rep(1:nfolds, length = self$n))
)
```

*Arguments:*

`nfolds` the number of folds  
`folds` a list of vectors describing the folds (optional)

*Returns:* a list with train and test data and id.

`DataModel$splitSubSamples()`: a function splitting data into subsamples

*Usage:*

```
DataModel$splitSubSamples(
  n_subsamples = 50,
  subsample_size = floor(self$n/2),
  subsamples = replicate(n_subsamples, sample(1:self$n, subsample_size), simplify =
    FALSE),
  weakness = 1
)
```

*Arguments:*

`n_subsamples` the number of subsamples

`subsample_size` the subsample size

`subsamples` list with vector of subsamples (optional)

`weakness` coefficient for randomly weighting the regressor, default to 1

*Returns:* a list of DataModel, resampling of the original

`DataModel$clone()`: The objects of this class are cloneable with this method.

*Usage:*

```
DataModel$clone(deep = FALSE)
```

*Arguments:*

`deep` Whether to make a deep clone.

---

deviance.QuadrupenFit *Extract model deviance*

---

**Description**

Extracts the deviance of a [QuadrupenFit](#) object

**Usage**

```
## S3 method for class 'QuadrupenFit'
deviance(object, ...)
```

**Arguments**

`object` a [QuadrupenFit](#) object

`...` not used, only here for S3 compatibility

**Value**

a scalar

---

`fitted.QuadrupeFit`     *Extracts model fitted values*

---

### Description

Extracts model fitted values

### Usage

```
## S3 method for class 'QuadrupeFit'
fitted(object, ...)
```

### Arguments

<code>object</code>	a <a href="#">QuadrupeFit</a> object
<code>...</code>	not used, only here for S3 compatibility

### Value

A matrix of fitted values extracted from object.

---

`FusedLassoFit`     *Class "FusedLassoFit"*

---

### Description

Class of object returned by the fitting function [fused\\_lasso\(\)](#). Inherits fields and methods of [QuadrupeFit](#).

### Super class

[QuadrupeFit](#) -> `FusedLassoFit`

### Active bindings

`penalty` character describing the regularizer/penalty  
`lambda1` vector of tuning parameters for the l1 penalty  
`lambda2` vector of tuning parameters for the fusion penalty

**Methods****Public methods:**

- [FusedLassoFit\\$new\(\)](#)
- [FusedLassoFit\\$clone\(\)](#)

[FusedLassoFit\\$new\(\)](#): Initialize a [FusedLassoFit](#) model

*Usage:*

```
FusedLassoFit$new(data, intercept, regParam)
```

*Arguments:*

data a [DataModel](#) object

intercept a logical; should an intercept be included in the mode?

regParam a list with two elements, a vector and a scalar, for the regularization

[FusedLassoFit\\$clone\(\)](#): The objects of this class are cloneable with this method.

*Usage:*

```
FusedLassoFit$clone(deep = FALSE)
```

*Arguments:*

deep Whether to make a deep clone.

fused\_lasso

*A function for fitting generalized fused-Lasso problems*

---

**Description**

This function fits the standard version of the fused lasso. It can take a general matrix  $x$  and allows for possible weights on the  $\lambda_1$  and  $\lambda_2$  penalties.

**Usage**

```
fused_lasso(
  x,
  y,
  lambda1 = NULL,
  lambda2 = 1,
  pen_fused = c("L1", "L2", "Huber"),
  penscale = rep(1, ncol(x)),
  struct = NULL,
  intercept = TRUE,
  normalize = TRUE,
  nlambda1 = ifelse(is.null(lambda1), 50, length(lambda1)),
```

```

minratio = 0.01,
maxfeat = ifelse(lambda2 < 1, min(nrow(x), ncol(x)), min(2 * nrow(x), ncol(x))),
beta0 = rep(0, ncol(x)),
control = list()
)

```

### Arguments

x	matrix of features, possibly sparsely encoded (experimental). Do NOT include intercept. When normalized is TRUE, coefficients will then be rescaled to the original scale.
y	response vector.
lambda1	sequence of decreasing $\ell_1$ -penalty levels. If NULL (the default), a vector is generated with nlambda1 entries, starting from a guessed level lambda1.max where only the intercept is included, then shrunken to minratio*lambda1.max.
lambda2	real scalar; tunes the $\ell_2$ penalty in the Elastic-net. Default is 0.01. Set to 0 to recover the Lasso.
pen_fused	penalty used for fusing the variables (either L1, L2 or Huber). Default is L1
penscale	vector with real positive values that weight the penalty of each feature. Default sets all weights to 1.
struct	Description of the graph that corresponds to the lambda2 penalty structure. If NULL (the default) a chain graph is assumed, like in the standard fused-lasso. If a matrix is given, interpreted as a symmetric adjacency matrix
intercept	logical; indicates if an intercept should be included in the model. Default is TRUE.
normalize	logical; indicates if variables should be normalized to have unit L2 norm before fitting. Default is TRUE.
nlambda1	integer that indicates the number of values to put in the lambda1 vector. Ignored if lambda1 is provided.
minratio	minimal value of $\ell_1$ -part of the penalty that will be tried, as a fraction of the maximal lambda1 value. A too small value might lead to instability at the end of the solution path corresponding to small lambda1 combined with $\lambda_2 = 0$ . The default value tries to avoid this, adapting to the ' $n < p$ ' context. Ignored if lambda1 is provided.
maxfeat	integer; limits the number of features ever to enter the model; i.e., non-zero coefficients for the Elastic-net: the algorithm stops if this number is exceeded and lambda1 is cut at the corresponding level. Default is $\min(\text{nrow}(x), \text{ncol}(x))$ for small lambda2 (<0.01) and $\min(4*\text{nrow}(x), \text{ncol}(x))$ otherwise. Use with care, as it considerably changes the computation time.
beta0	a starting point for the vector of parameter. By default, will initialized zero. May save time in some situation.
control	list of argument controlling low level options of the algorithm: <ul style="list-style-type: none"> <li>• verbose: logical; verbose mode</li> <li>• timer: logical; use to record the timing of the algorithm. Default is FALSE.</li> </ul>

- `maxiterin` Maximum number of iterations in the inner loop to run.
- `maxiterout` Maximum number of iterations in the outer loop to run.
- `maxactivation` Maximum number of previously inactive variables to activate at the same time
- `accuracy` Accuracy at which the algorithm will stop.
- `fusioncheck` Should the fused sets be checked for separation?
- `verbose` Should the function give some output what it is doing?

## Details

The optimized criterion is the following:

$$\hat{\beta}_{\lambda_1, \lambda_2} = \arg \min_{\beta} \frac{1}{2} (y - X\beta)^T (y - X\beta) + \lambda_1 \|w \circ \beta\|_1 + \frac{\lambda_2}{2} \sum_{i \sim j} w_{ij} |\beta_i - \beta_j|,$$

where  $D$  is a diagonal matrix, whose diagonal terms are provided as a vector by the `penscale` argument. The  $\ell_1$  fusion penalty is structured by a possibly weighted graph  $G$  provided via the `struct` argument, as a symmetric (undirected) adjacency matrix.

## Value

an object with class `FusedLassoFit`, inheriting from `QuadrupenFit`.

## Author(s)

Original code by Holger Hoefling, refactoring by Julien Chiquet

## Examples

```
beta <- rep(c(0,1,0,-1,0), c(25,10,25,10,25))
cor <- 0.75
Soo <- toeplitz(cor^(0:(25-1))) ## Toeplitz correlation for irrelevant variables
Sww <- matrix(cor,10,10) ## bloc correlation between active variables
Sigma <- Matrix::bdiag(Soo,Sww,Soo,Sww,Soo)
diag(Sigma) <- 1
n <- 50
x <- as.matrix(matrix(rnorm(95*n),n,95) %%% chol(Sigma))
y <- 10 + x %%% beta + rnorm(n,0,10)

res <- fused_lasso(x, y, lambda2=5)
G <- igraph::make_ring(ncol(x)) |> igraph::as_adjacency_matrix(sparse = FALSE)
resG <- fused_lasso(x, y, lambda2=5, struct = G)
plot(res)
plot(resG)
```

---

GroupLavaFit	Class "GroupLavaFit"
--------------	----------------------

---

### Description

Class of object returned by the fitting function `group_lava()`. Inherits fields and methods of [QuadrupenFit](#) and [LavaFit](#)

### Super classes

[QuadrupenFit](#) -> [LavaFit](#) -> GroupLavaFit

### Active bindings

`lambda1` vector of tuning parameters for the  $l_1$  group penalty (sparse component)  
`lambda2` vector of tuning parameters for the  $l_2$  penalty (dense component)  
`penalty` character describing the regularizer/penalty  
`group` vector of integers indicating group belonging  
`type` string indicating whether the  $l_1/l_2$  or the  $l_1/l_\infty$  group-Lasso must be fitted.

### Methods

#### Public methods:

- [GroupLavaFit\\$new\(\)](#)
- [GroupLavaFit\\$clone\(\)](#)

`GroupLavaFit$new()`: Initialize a [GroupLavaFit](#) model

*Usage:*

`GroupLavaFit$new(data, intercept, group, type, regParam)`

*Arguments:*

`data` a [DataModel](#) object  
`intercept` a logical; should an intercept be included in the mode?  
`group` vector of integers indicating group belonging.  
`type` string indicating whether the  $l_1/l_2$  or the  $l_1/l_\infty$  group-Lasso must be fitted.  
`regParam` a list with two elements, a vector and a scalar, for the regularization

`GroupLavaFit$clone()`: The objects of this class are cloneable with this method.

*Usage:*

`GroupLavaFit$clone(deep = FALSE)`

*Arguments:*

`deep` Whether to make a deep clone.

### See Also

group\_lava

*Fit a linear model with group-lava regularization***Description**

Adjust a the group-lava regularized linear models, that is a lava transformation of the data plus a mixture of either a (possibly weighted)  $\ell_1/\ell_2$ - or  $\ell_1/\ell_\infty$ -norm, and a (possibly structured)  $\ell_2$ -norm (ridge-like). The solution path is computed at a grid of values for the  $\ell_1/\ell_q$ -penalty. See details for the criterion optimized.

**Usage**

```
group_lava(
  x,
  y,
  group,
  type = c("l2", "coop", "linf"),
  lambda1 = NULL,
  lambda2 = 1,
  weights = rep(1, nrow(x)),
  penscale = sqrt(tabulate(group)),
  struct = Matrix::Diagonal(ncol(x), 1),
  intercept = TRUE,
  normalize = TRUE,
  refit = FALSE,
  nlambda1 = ifelse(is.null(lambda1), 100, length(lambda1)),
  minratio = 0.01,
  maxfeat = ifelse(lambda2 < 0.01, min(nrow(x), ncol(x)), min(4 * nrow(x), ncol(x))),
  beta0 = numeric(ncol(x)),
  control = list()
)
```

**Arguments**

x	matrix of features, possibly sparsely encoded (experimental). Do NOT include intercept. When normalized is TRUE, coefficients will then be rescaled to the original scale.
y	response vector.
group	vector of integers indicating group belonging. Must match the number of column in x. Must be SORTED integers starting from 1.
type	string indicating whether the $\ell_1/\ell_2$ or the $\ell_1/\ell_\infty$ group-Lasso must be fitted. Could be "linf" or "l2", default is "l2"
lambda1	sequence of decreasing $\ell_1$ -penalty levels. If NULL (the default), a vector is generated with nlambda1 entries, starting from a guessed level lambda1.max where only the intercept is included, then shrunken to minratio*lambda1.max.

lambda2	real scalar; tunes the $\ell_2$ penalty in the Elastic-net. Default is 0.01. Set to 0 to recover the Lasso.
weights	vector with real positive values that weight the observations (like in weighted least square). Default sets all weights to 1.
penscale	vector with real positive values that weight the penalty of each feature. Default sets all weights to 1.
struct	matrix structuring the coefficients, possibly sparsely encoded. Must be at least positive semidefinite (this is checked internally). If NULL (the default), the identity matrix is used. See details below.
intercept	logical; indicates if an intercept should be included in the model. Default is TRUE.
normalize	logical; indicates if variables should be normalized to have unit L2 norm before fitting. Default is TRUE.
refit	logical: indicates if the non null coefficients should be refit to avoid excessive bias. Default is FALSE. Can be changed later (both raw and refit coefficients are stored).
nlambda1	integer that indicates the number of values to put in the lambda1 vector. Ignored if lambda1 is provided.
minratio	minimal value of $\ell_1$ -part of the penalty that will be tried, as a fraction of the maximal lambda1 value. A too small value might lead to instability at the end of the solution path corresponding to small lambda1 combined with $\lambda_2 = 0$ . The default value tries to avoid this, adapting to the ' $n < p$ ' context. Ignored if lambda1 is provided.
maxfeat	integer; limits the number of features ever to enter the model; i.e., non-zero coefficients for the Elastic-net: the algorithm stops if this number is exceeded and lambda1 is cut at the corresponding level. Default is $\min(\text{nrow}(x), \text{ncol}(x))$ for small lambda2 ( $< 0.01$ ) and $\min(4 * \text{nrow}(x), \text{ncol}(x))$ otherwise. Use with care, as it considerably changes the computation time.
beta0	a starting point for the vector of parameter. By default, will initialized zero. May save time in some situation.
control	list of argument controlling low level options of the algorithm –use with care and at your own risk– : <ul style="list-style-type: none"> <li>• verbose: integer; activate verbose mode –this one is not too risky!– set to 0 for no output; 1 for warnings only, and 2 for tracing the whole progression. Default is 1. Automatically set to 0 when the method is embedded within cross-validation or stability selection.</li> <li>• timer: logical; use to record the timing of the algorithm. Default is FALSE.</li> <li>• maxiter the maximal number of iteration used in the active set algorithm to solve the problem for a given value of lambda1 . Default is 50.</li> <li>• method a string for the underlying solver used. Either "quadra", "fista" or "pgd". Default is "quadra".</li> <li>• factmat Boolean indicating if matrix factorization should be used to solve the sub-system. If TRUE (the default), a Cholesky decomposition is maintained along the path. If FALSE, the sub-system are solved with a conjugate gradient algorithm.</li> </ul>

- threshold a threshold for convergence. The algorithm stops when the optimality conditions are fulfilled up to this threshold. Default is 1e-6.
- monitor indicates if a monitoring of the convergence should be recorded, by computing a lower bound between the current solution and the optimum: when '0' (the default), no monitoring is provided; when '1', the bound derived in Grandvalet et al. is computed; when '>1', the Fenchel duality gap is computed along the algorithm.

## Details

The optimized criterion is the following:

$$\hat{\theta}_{\lambda_1, \lambda_2} = \arg \min_{\theta = \beta + \delta} \frac{1}{2n} (y - X(\beta + \delta))^T (y - X(\beta + \delta)) + \lambda_1 \Omega_g(\beta) + \frac{\lambda_2}{2} \delta^T S \delta,$$

where  $\Omega_g$  is the group-wise mixed norm:  $\ell_1/\ell_2$  (Group-LAVA) or  $\ell_1/\ell_\infty$ , controlled by the type argument. The  $\ell_2$  structuring matrix  $S$  is provided via `struct`.

## Value

an object with class `GroupLavaFit`, inheriting from `QuadrupenFit`.

---

group\_sparse\_lm

*Fit a linear model with (sparse) group regularisation*

---

## Description

Adjust a linear model with (sparse) group regularization, that is, a mixture of an element-wise  $\ell_1$  norm and a group-wise mixed-norm (either  $\ell_1/\ell_2$ ,  $\ell_1/\ell_\infty$  or cooperative). We also add a (possibly structured)  $\ell_2$ -norm (ridge-like). The solution path is computed on an automatically tuned grid of values for the sparse group penalty. The mixture coefficient and the amount of ridge-like regularization are fixed by the user. See details for the criterion optimized.

## Usage

```

```

### Arguments

x	matrix of features, possibly sparsely encoded (experimental). Do NOT include intercept. When normalized is TRUE, coefficients will then be rescaled to the original scale.
y	response vector.
group	vector of integers indicating group belonging. Must match the number of column in x. Must be SORTED integers starting from 1.
type	string indicating the sparse-group variant to be fitted. Could be "l2", "coop", or "l1". Default is "l2" (regular Group-Lasso)
lambda1	sequence of decreasing $\ell_1$ -penalty levels. If NULL (the default), a vector is generated with nlambda1 entries, starting from a guessed level lambda1.max where only the intercept is included, then shrunken to minratio*lambda1.max.
lambda2	real scalar; tunes the $\ell_2$ penalty in the Elastic-net. Default is 0.01. Set to 0 to recover the Lasso.
alpha	real scalar in (0,1); tunes mixture between $\ell_1$ group penalties. Default is 0.0 (standard group-lasso).
weights	vector with real positive values that weight the observations (like in weighted least square). Default sets all weights to 1.
penscale	vector with real positive values that weight the penalty of each feature. Default sets all weights to 1.
struct	matrix structuring the coefficients, possibly sparsely encoded. Must be at least positive semidefinite (this is checked internally). If NULL (the default), the identity matrix is used. See details below.
intercept	logical; indicates if an intercept should be included in the model. Default is TRUE.
normalize	logical; indicates if variables should be normalized to have unit L2 norm before fitting. Default is TRUE.
refit	logical: indicates if the non null coefficients should be refit to avoid excessive bias. Default is FALSE. Can be changed later (both raw and refit coefficients are stored).
nlambda1	integer that indicates the number of values to put in the lambda1 vector. Ignored if lambda1 is provided.

minratio	minimal value of $\ell_1$ -part of the penalty that will be tried, as a fraction of the maximal lambda1 value. A too small value might lead to instability at the end of the solution path corresponding to small lambda1 combined with $\lambda_2 = 0$ . The default value tries to avoid this, adapting to the ' $n < p$ ' context. Ignored if lambda1 is provided.
maxfeat	integer; limits the number of features ever to enter the model; i.e., non-zero coefficients for the Elastic-net: the algorithm stops if this number is exceeded and lambda1 is cut at the corresponding level. Default is $\min(\text{nrow}(x), \text{ncol}(x))$ for small lambda2 ( $< 0.01$ ) and $\min(4 * \text{nrow}(x), \text{ncol}(x))$ otherwise. Use with care, as it considerably changes the computation time.
beta0	a starting point for the vector of parameter. By default, will initialized zero. May save time in some situation.
control	list of argument controlling low level options of the algorithm –use with care and at your own risk– : <ul style="list-style-type: none"> <li>• verbose: integer; activate verbose mode –this one is not too risky!– set to 0 for no output; 1 for warnings only, and 2 for tracing the whole progression. Default is 1. Automatically set to 0 when the method is embedded within cross-validation or stability selection.</li> <li>• timer: logical; use to record the timing of the algorithm. Default is FALSE.</li> <li>• maxiter the maximal number of iteration used in the active set algorithm to solve the problem for a given value of lambda1 . Default is 50.</li> <li>• method a string for the underlying solver used. Either "quadra", "fista" or "pgd". Default is "quadra".</li> <li>• factmat Boolean indicating if matrix factorization should be used to solve the sub-system. If TRUE (the default), a Cholesky decomposition is maintained along the path. If FALSE, the sub-system are solved with a conjugate gradient algorithm.</li> <li>• threshold a threshold for convergence. The algorithm stops when the optimality conditions are fulfill up to this threshold. Default is <math>1e-6</math>.</li> <li>• monitor indicates if a monitoring of the convergence should be recorded, by computing a lower bound between the current solution and the optimum: when '0' (the default), no monitoring is provided; when '1', the bound derived in Grandvalet et al. is computed; when '&gt;1', the Fenchel duality gap is computed along the algorithm.</li> </ul>

## Details

The optimized criterion is the following:

$$\hat{\beta}_{\lambda_1, \lambda_2} = \arg \min_{\beta} \frac{1}{2} (y - X\beta)^T (y - X\beta) + \lambda_1 [(1 - \alpha) \Omega_g(\beta) + \alpha \|D\beta\|_1] + \frac{\lambda_2}{2} \beta^T S \beta,$$

where  $\Omega_g$  is the group-wise mixed norm:  $\ell_1/\ell_2$  (Group-Lasso),  $\ell_1/\ell_\infty$ , or cooperative (Clime), controlled by the type argument;  $D$  is a diagonal matrix whose diagonal terms are given by penscale;  $\alpha$  tunes the mixture between the group and element-wise penalties; and  $S$  is the  $\ell_2$  structuring matrix provided via struct, a positive semidefinite matrix (possibly of class Matrix).

InformationCriteria    *Class InformationCriteria*

---

## Description

Class of object returned by the `QuadrupenFit$criteria()` method or the `criteria()` function. Owns `print()` and `plot()` methods.

## Active bindings

`data` a data frame containing the values of various information criteria (AIC, BIC, lmbBIC, eBIC, GCV) along the value of `lambda1`.

`lambda` vector of  $\lambda_1$  ( $\ell_1$  or  $\ell_\infty$  penalty levels) for which each cross-validation has been performed.

`names` a vector of characters storing the names of the precomputed criteria

## Methods

### Public methods:

- `InformationCriteria$new()`
- `InformationCriteria$show()`
- `InformationCriteria$print()`
- `InformationCriteria$plot()`
- `InformationCriteria$clone()`

`InformationCriteria$new()`: Constructor for a `InformationCriteria` object Should be called internally by an object `QuadrupenFit$criteria()`

*Usage:*

```
InformationCriteria$new(value)
```

*Arguments:*

value data frame storing output of `QuadrupenFit$criteria()`

`InformationCriteria$show()`: User friendly print method

*Usage:*

```
InformationCriteria$show()
```

`InformationCriteria$print()`: User friendly print method

*Usage:*

```
InformationCriteria$print()
```

`InformationCriteria$plot()`: Plot the the desired criteria

*Usage:*

```
InformationCriteria$plot(
  criteria = self$names,
  log_scale = TRUE,
  xvar = c("lambda", "fraction", "df"),
  title = "Information Criteria"
)
```

*Arguments:*

criteria a vector of character with the criteria to plot. The default plot all the criteria available (stored in the field names)

log\_scale logical; indicates if a log-scale should be used when xvar="lambda". Default is TRUE.

xvar variable to plot on the X-axis: either "df" (the estimated degrees of freedom), "lambda" ( $\lambda_1$  penalty level) or "fraction" ( $\ell_1$ -norm of the coefficients). Default is set to "lambda".

title graph title

*Returns:* a **ggplot2** object

`InformationCriteria$clone()`: The objects of this class are cloneable with this method.

*Usage:*

```
InformationCriteria$clone(deep = FALSE)
```

*Arguments:*

deep Whether to make a deep clone.

---

isQuadrupenFit	<i>Auxiliary functions to check the given class of an object</i>
----------------	--

---

**Description**

Auxiliary functions to check the given class of an object

**Usage**

```
isQuadrupenFit(Robject)
```

**Arguments**

Robject            an R object to evaluate

**Value**

logical

---

lava	<i>Fit a linear model with lava regularization</i>
------	--

---

**Description**

Adjust a lava regularized linear model, that is a lava transformation of the data followed by a (possibly weighted)  $\ell_1$ -norm. The solution path is computed at a grid of values for the  $\ell_1$ -penalty. See details for the criterion optimized.

**Usage**

```
lava(
  x,
  y,
  lambda1 = NULL,
  lambda2 = 1,
  weights = rep(1, nrow(x)),
  penscale = rep(1, ncol(x)),
  struct = Matrix::Diagonal(ncol(x), 1),
  intercept = TRUE,
  normalize = TRUE,
  refit = FALSE,
  nlambda1 = ifelse(is.null(lambda1), 100, length(lambda1)),
  minratio = 0.01,
  maxfeat = min(nrow(x), ncol(x)),
  beta0 = numeric(ncol(x)),
  control = list()
)
```

**Arguments**

x	matrix of features, possibly sparsely encoded (experimental). Do NOT include intercept. When normalized is TRUE, coefficients will then be rescaled to the original scale.
y	response vector.
lambda1	sequence of decreasing $\ell_1$ -penalty levels. If NULL (the default), a vector is generated with nlambda1 entries, starting from a guessed level lambda1.max where only the intercept is included, then shrunken to minratio*lambda1.max.
lambda2	real scalar; tunes the $\ell_2$ penalty in the Elastic-net. Default is 0.01. Set to 0 to recover the Lasso.
weights	vector with real positive values that weight the observations (like in weighted least square). Default sets all weights to 1.
penscale	vector with real positive values that weight the penalty of each feature. Default sets all weights to 1.
struct	matrix structuring the coefficients, possibly sparsely encoded. Must be at least positive semidefinite (this is checked internally). If NULL (the default), the identity matrix is used. See details below.
intercept	logical; indicates if an intercept should be included in the model. Default is TRUE.
normalize	logical; indicates if variables should be normalized to have unit L2 norm before fitting. Default is TRUE.
refit	logical: indicates if the non null coefficients should be refit to avoid excessive bias. Default is FALSE. Can be changed later (both raw and refit coefficients are stored).
nlambda1	integer that indicates the number of values to put in the lambda1 vector. Ignored if lambda1 is provided.
minratio	minimal value of $\ell_1$ -part of the penalty that will be tried, as a fraction of the maximal lambda1 value. A too small value might lead to instability at the end of the solution path corresponding to small lambda1 combined with $\lambda_2 = 0$ . The default value tries to avoid this, adapting to the ' $n < p$ ' context. Ignored if lambda1 is provided.
maxfeat	integer; limits the number of features ever to enter the model; i.e., non-zero coefficients for the Elastic-net: the algorithm stops if this number is exceeded and lambda1 is cut at the corresponding level. Default is $\min(\text{nrow}(x), \text{ncol}(x))$ for small lambda2 (<0.01) and $\min(4*\text{nrow}(x), \text{ncol}(x))$ otherwise. Use with care, as it considerably changes the computation time.
beta0	a starting point for the vector of parameter. By default, will initialized zero. May save time in some situation.
control	list of argument controlling low level options of the algorithm –use with care and at your own risk– : <ul style="list-style-type: none"> <li>• verbose: integer; activate verbose mode –this one is not too risky!– set to 0 for no output; 1 for warnings only, and 2 for tracing the whole progression. Default is 1. Automatically set to 0 when the method is embedded within cross-validation or stability selection.</li> </ul>

- `timer`: logical; use to record the timing of the algorithm. Default is FALSE.
- `maxiter` the maximal number of iteration used in the active set algorithm to solve the problem for a given value of `lambda1` . Default is 50.
- `method` a string for the underlying solver used. Either "quadra", "fista" or "pgd". Default is "quadra".
- `factmat` Boolean indicating if matrix factorization should be used to solve the sub-system. If TRUE (the default), a Cholesky decomposition is maintained along the path. If FALSE, the sub-system are solved with a conjugate gradient algorithm.
- `threshold` a threshold for convergence. The algorithm stops when the optimality conditions are fulfill up to this threshold. Default is 1e-6.
- `monitor` indicates if a monitoring of the convergence should be recorded, by computing a lower bound between the current solution and the optimum: when '0' (the default), no monitoring is provided; when '1', the bound derived in Grandvalet et al. is computed; when '>1', the Fenchel duality gap is computed along the algorithm.

## Details

The optimized criterion is the following:

$$\hat{\theta}_{\lambda_1, \lambda_2} = \arg \min_{\theta = \beta + \delta} \frac{1}{2n} (y - X(\beta + \delta))^T (y - X(\beta + \delta)) + \lambda_1 \|\beta\|_1 + \frac{\lambda_2}{2} \delta^T S \delta,$$

## Value

an object with class `QuadrupenFit`.

an object with class `LavaFit`, inheriting from `QuadrupenFit`.

```

```

labels <- rep("irrelevant", length(beta))
labels[beta != 0] <- "relevant"
## The solution path of the LAVA
out <- lava(x,y)
out$plot_path(component = "sparse", labels=labels)
out$plot_path(component = "dense", labels=labels)

```

---

LavaFit

*Class "LavaFit"*

---

## Description

Class of object returned by the fitting function [lava\(\)](#). Inherits fields and methods of [QuadrupenFit](#)

## Super class

[QuadrupenFit](#) -> LavaFit

## Active bindings

penalty character describing the regularizer/penalty

lambda1 vector of tuning parameters for the l1 penalty (sparse component)

lambda2 vector of tuning parameters for the l2 penalty (dense component)

sparse\_coef sparse part of the decomposition of the coefficients

dense\_coef dense part of the decomposition of the coefficients

debias logical, should we rely on the debias coefficient of the regularizer (if available) or not

## Methods

### Public methods:

- [LavaFit\\$new\(\)](#)
- [LavaFit\\$fit\(\)](#)
- [LavaFit\\$plot\\_path\(\)](#)
- [LavaFit\\$clone\(\)](#)

[LavaFit\\$new\(\)](#): Initialize a [LavaFit](#) model

*Usage:*

```
LavaFit$new(data, intercept, regParam)
```

*Arguments:*

data a [DataModel](#) object

intercept a logical; should an intercept be included in the mode?

regParam a list with two elements, a vector and a scalar, for the regularization

`LavaFit$fit()`: function performing the optimization

*Usage:*

```
LavaFit$fit(control)
```

*Arguments:*

`control` list controlling the optimization process Plot method for lava regularization path

`LavaFit$plot_path()`: Produce a plot of the solution path of a [LavaFit](#) object.

*Usage:*

```
LavaFit$plot_path(
  xvar = c("lambda", "fraction", "df"),
  log_scale = TRUE,
  component = "both",
  title = paste("Lava path:", component, "component(s)"),
  standardize = TRUE,
  labels = NULL
)
```

*Arguments:*

`xvar` variable to plot on the X-axis: either "lambda" ( $\ell_1$  penalty level, or  $\ell_2$  for ridge and  $\ell_\infty$ ) or "fraction" ( $\ell_1$ -norm of the coefficients) or df for estimated degrees of freedom. Default is set to "lambda".

`log_scale` logical; indicates if a log-scale should be used when `xvar="lambda"`. Default is TRUE.

`component` a character indicating the component to plot: both (sum of sparse and dense), sparse or dense. Default to both.

`title` the title. Default is set to the model name followed by what is on the Y-axis.

`standardize` logical; standardize the coefficients before plotting (with the norm of the predictor). Default is TRUE.

`labels` vector indicating the names associated to the plotted variables. When specified, a legend is drawn in order to identify each variable. Only relevant when the number of predictor is small. Remind that the intercept does not count. Default is NULL.

*Returns:* a **ggplot2** object .

`LavaFit$clone()`: The objects of this class are cloneable with this method.

*Usage:*

```
LavaFit$clone(deep = FALSE)
```

*Arguments:*

`deep` Whether to make a deep clone.

plot.QuadrupenFit      *Plot method for quadrupen objects*

---

### Description

S3 plot methods for [QuadrupenFit](#), [CrossValidation](#) and [StabilityPath](#) objects, delegating to their respective R6 \$plot() method.

### Usage

```
## S3 method for class 'QuadrupenFit'  
plot(x, ...)  
  
## S3 method for class 'CrossValidation'  
plot(x, ...)  
  
## S3 method for class 'StabilityPath'  
plot(x, ...)
```

### Arguments

x                    a [QuadrupenFit](#), [CrossValidation](#) or [StabilityPath](#) object.  
...                  additional arguments passed to the underlying R6 \$plot() method. For [QuadrupenFit](#): type ("path", "criteria", "crossval", "stability"), log\_scale, labels. For [CrossValidation](#): log\_scale, title. For [StabilityPath](#): xvar, title, labels, sel\_mode, cutoff, PFER, nvarsel.

### Value

a **ggplot2** object.

### Functions

- plot(CrossValidation): Plot method for a [CrossValidation](#) object
- plot(StabilityPath): Plot method for a [StabilityPath](#) object

---

predict.QuadrupenFit      *Perform model prediction*

---

### Description

Predict response for new sample based on the current model

**Usage**

```
## S3 method for class 'QuadrupenFit'
predict(object, newx = NULL, selection = NULL, ...)
```

**Arguments**

object	an R object to evaluate
newx	matrix of new values for the regressor with which to predict. If omitted, the fitted values are used.
selection	either a character (model selection criteria) of a scalar (lambda value)
...	not used, only here for S3 compatibility

**Value**

a vector of predicted value

---

QuadrupenFit	<i>Class "QuadrupenFit"</i>
--------------	-----------------------------

---

**Description**

Class of object returned by any fitting function of the **quadrupen** package (`elastic_net` or `bounded_reg`).

This class comes with the usual `predict()`, `fitted()`, `coef()`, `residuals()`, `show()`, `print()` and `deviance()` S3 methods.

Specific R6 methods are available for model extraction `QuadrupenFit$get_model()`, cross validation `QuadrupenFit$cross_validate()`, stability selection `QuadrupenFit$stability_path()`, criteria derivation `QuadrupenFit$criteria()` and plotting `QuadrupenFit$plot()`. They come with equivalent S3 methods: `cross_validate()`, `stability()` and `plot()`.

The "path" plot is available as soon as a fit has been performed. For the others, the appropriate post-treatments must have been made via the methods `QuadrupenFit$criteria()`, `QuadrupenFit$cross_validate()` or `QuadrupenFit$stability()`

All plots functions are given with the default arguments, except for labels and `log_scale`. If you need more control, please use the dedicated methods: `QuadrupenFit$plot_path()`, `InformationCriteria$plot()`, `CrossValidation$plot()`, `StabilityPath$plot()` or the corresponding S3 methods.

Plot method for regularization path

**Active bindings**

nvar	number of coefficient (without intercept)
nobs	sample size
dataModel	an object with class <code>DataModel</code> storing the data
major_tuning	vector of "leading" tuning parameters (either l1, l1nf or l2)
minor_tuning	vector of "minor" tuning parameters (either l1 or l2)

is\_l2\_regularized Boolean indicating if l2 regularization is applied  
 optim\_monitoring list monitoring the optimization  
 optim\_config list with low level options used for optimization.  
 fitted Matrix of fitted values, each column corresponding to a value of lambda1.  
 coefficients Matrix (class "dgCMatrix") of coefficients with respect to the original input. The number of rows corresponds the length of lambda1.  
 intercept A vector containing the successive values of the (unpenalized) intercept. Equals to zero if intercept has been set to FALSE.  
 debias logical, should we rely on the debias coefficient of the regularizer (if available) or not  
 residuals Matrix of residuals, each column corresponding to a value of lambda1.  
 deviance the model deviance  
 degrees\_freedom Estimated degree of freedoms for the successive lambda1.  
 r\_squared vector giving the coefficient of determination as a function of lambda1.  
 information\_criteria object with class [InformationCriteria](#) storing various information criteria (AIC, BIC, GCV, etc) for the current fit.  
 cross\_validation object with class [CrossValidation](#) storing output of CV job. Only available once method cross\_validate has been called.  
 stability\_path object with class [StabilityPath](#) storing output of stability selection. Only available once method \$stability has been called.

## Methods

### Public methods:

- [QuadrupenFit\\$new\(\)](#)
- [QuadrupenFit\\$show\(\)](#)
- [QuadrupenFit\\$print\(\)](#)
- [QuadrupenFit\\$fit\(\)](#)
- [QuadrupenFit\\$get\\_model\(\)](#)
- [QuadrupenFit\\$predict\(\)](#)
- [QuadrupenFit\\$cross\\_validate\(\)](#)
- [QuadrupenFit\\$stability\(\)](#)
- [QuadrupenFit\\$criteria\(\)](#)
- [QuadrupenFit\\$plot\(\)](#)
- [QuadrupenFit\\$plot\\_path\(\)](#)
- [QuadrupenFit\\$clone\(\)](#)

[QuadrupenFit\\$new\(\)](#): Initialize a [QuadrupenFit](#) model

*Usage:*

`QuadrupenFit$new(data, intercept, regParam)`

*Arguments:*

data a [DataModel](#) object

intercept a logical; should an intercept be included in the mode?

regParam a list with two elements, a vector and a scalar, for the regularization

QuadrupenFit\$show(): User friendly print method

*Usage:*

QuadrupenFit\$show()

QuadrupenFit\$print(): User friendly print method

*Usage:*

QuadrupenFit\$print()

QuadrupenFit\$fit(): function performing the optimization

*Usage:*

QuadrupenFit\$fit(control)

*Arguments:*

control list controlling the optimization process

QuadrupenFit\$get\_model(): Model extraction

*Usage:*

QuadrupenFit\$get\_model(selection, type = c("coefficients", "penalty", "index"))

*Arguments:*

selection either a character (model selection criteria) or a scalar (lambda value)

type character for the desired output

*Returns:* either a vector of coefficients, a scalar or the model index

QuadrupenFit\$predict(): Predict response for new sample based on the current model

*Usage:*

QuadrupenFit\$predict(newx = NULL, selection = NULL)

*Arguments:*

newx matrix of new values for the regressor with which to predict. If omitted, the fitted values are used.

selection either a character (model selection criteria) or a scalar (lambda value)

*Returns:* a vector of predicted value Cross-validation for Quadrupen object

QuadrupenFit\$cross\_validate(): Function that computes K-fold cross-validated error of a quadrupen fit, possibly on a grid of lambda1, lambda2.

*Usage:*

```
QuadrupenFit$cross_validate(
  K = 10,
  folds = split(sample(1:self$nobs), rep(1:K, length = self$nobs)),
  lambda2 = self$minor_tuning,
  verbose = TRUE,
  cores = 1
)
```

*Arguments:*

- K integer indicating the number of folds. Default is 10.
- folds list of K vectors that describes the folds to use for the cross-validation. By default, the folds are randomly sampled with the specified K. The same folds are used for each values of lambda2.
- lambda2 tunes the  $\ell_2$ -penalty (ridge-like) of the fit. If none is provided, a vector of values is generated and a CV is performed on a grid of lambda2 and lambda1, using the same folds for each lambda2.
- verbose logical; indicates if the progression (the current lambda2 should be displayed. Default is TRUE.
- cores the number of cores to use. The default uses 1 core (safer in case your BLAS/LAPACK libraries are multithreaded)

*Returns:* an object with class [CrossValidation](#) is sent back and stored as a field of the original [QuadrupenFit](#) object.

`QuadrupenFit$stability()`: Compute the stability path of a (possibly randomized) fitting procedure as introduced by Meinshausen and Bühlmann (2010).

*Usage:*

```

QuadrupenFit$stability(
  n_subsamples = 50,
  subsample_size = floor(self$nobs/2),
  subsamples = replicate(n_subsamples, sample(1:self$nobs, subsample_size), simplify =
    FALSE),
  weakness = 1,
  verbose = TRUE,
  cores = 1
)

```

*Arguments:*

- n\_subsamples integer indicating the number of subsamplings used to estimate the selection probabilities. Default is 100.
- subsample\_size integer indicating the size of each subsamples. Default is floor(n/2).
- subsamples list with subsamples entries with vectors describing the folds to use for the stability procedure. By default, the folds are randomly sampled with the specified n\_subsamples and subsample\_size argument.
- weakness Coefficient used for randomizing the weights of each features. Default is 1' for no randomization. See details below.
- verbose logical; indicates if the progression should be displayed. Default is TRUE.
- cores the number of cores to use. The default uses 1 core (safer in case your BLAS/LAPACK libraries are multithreaded)

*Returns:* an object with class [StabilityPath](#) is sent back and stored as a field of the original [QuadrupenFit](#) object.

`QuadrupenFit$criteria()`: Produce a plot or send back the values of some penalized criteria accompanied with the vector(s) of parameters selected accordingly. The default behavior plots the BIC and the AIC (with respective factor  $\log(n)$  and 2) yet the user can specify any penalty.

*Usage:*

```
QuadrupenFit$criteria(
  penalty = setNames(c(2, log(self$nobs), log(self$nvar), log(self$nobs) + 2 *
    log(self$nvar)), c("AIC", "BIC", "mBIC", "eBIC")),
  sigma = NULL
)
```

*Arguments:*

`penalty` a vector with as many penalties as desired. The default contains the penalty corresponding to the AIC and the BIC (2 and  $\log(n)$ ). Setting the "names" attribute, as done in the default definition, leads to outputs which are easier to read.

`sigma` scalar: an estimate of the residual variance. When available, it is plugged-in the criteria, which may be more relevant. If NULL (the default), it is estimated as usual (see details).

*Returns:* an object with class `InformationCriteria` is sent back and stored as a field of the original `QuadrupenFit` object.

`QuadrupenFit$plot()`: Plot method for `QuadrupenFit`

*Usage:*

```
QuadrupenFit$plot(
  type = c("path", "criteria", "crossval", "stability"),
  log_scale = TRUE,
  labels = NULL
)
```

*Arguments:*

`type` the type of plot, either "path" for regularization path; "criteria" for BIC-like information criteria; "crossval" for cross-validation plot; and "stability" for stability path.

`log_scale` logical; indicates if a log-scale should be used when `xvar="lambda"`. Default is TRUE.

`labels` vector indicating the names associated to the plotted variables. When specified, a legend is drawn in order to identify each variable. Only relevant when the number of predictor is small. Remind that the intercept does not count. Default is NULL.

`QuadrupenFit$plot_path()`: Produce a plot of the solution path of a `QuadrupenFit` object.

*Usage:*

```
QuadrupenFit$plot_path(
  xvar = c("lambda", "fraction", "df"),
  log_scale = TRUE,
  title = paste("Path for", self$penalty),
  standardize = TRUE,
  labels = NULL
)
```

*Arguments:*

`xvar` variable to plot on the X-axis: either "lambda" ( $\ell_1$  penalty level, or  $\ell_2$  for ridge and  $\ell_\infty$ ) or "fraction" ( $\ell_1$ -norm of the coefficients) or `df` for estimated degrees of freedom. Default is set to "lambda".

`log_scale` logical; indicates if a log-scale should be used when `xvar="lambda"`. Default is TRUE.

`title` the title. Default is set to the model name followed by what is on the Y-axis.

`standardize` logical; standardize the coefficients before plotting (with the norm of the predictor). Default is TRUE.

`labels` vector indicating the names associated to the plotted variables. When specified, a legend is drawn in order to identify each variable. Only relevant when the number of predictor is small. Remind that the intercept does not count. Default is NULL.

*Returns:* a **ggplot2** object.

*Examples:*

```
## Simulating multivariate Gaussian with blockwise correlation
## and piecewise constant vector of parameters
beta <- rep(c(0,1,0,-1,0), c(25,10,25,10,25))
cor <- 0.75
Soo <- toeplitz(cor^(0:(25-1))) ## Toeplitz correlation for irrelevant variables
Sww <- matrix(cor,10,10) ## bloc correlation between active variables
Sigma <- bdiag(Soo,Sww,Soo,Sww,Soo)
diag(Sigma) <- 1
n <- 50
x <- as.matrix(matrix(rnorm(95*n),n,95) %*% chol(Sigma))
y <- 10 + x %*% beta + rnorm(n,0,10)

## Plot the Lasso path
plot(lasso(x,y), title="Lasso solution path")
## Plot the Elastic-net path
plot(elastic_net(x,y), title = "Elastic-net solution path")
## Plot the Elastic-net path (fraction on X-axis, unstandardized coefficient)
plot(elastic_net(x,y, lambda2=10), standardize=FALSE, xvar="fraction")
## Plot the Bounded regression path (fraction on X-axis)
plot(bounded_reg(x,y, lambda2=10), xvar="fraction")
```

`QuadrupenFit$clone()`: The objects of this class are cloneable with this method.

*Usage:*

```
QuadrupenFit$clone(deep = FALSE)
```

*Arguments:*

`deep` Whether to make a deep clone.

residuals.QuadrupenFit

*Extract model residuals*

---

**Description**

Extracts model residuals from a [QuadrupenFit](#) object

**Usage**

```
## S3 method for class 'QuadrupenFit'
residuals(object, newx = NULL, newy = NULL, ...)
```

**Arguments**

object	a <a href="#">QuadrupenFit</a> object
newx	matrix of new covariates for out-of-sample residuals. Must be provided together with newy. If NULL (default), training residuals are returned.

newy	vector of new responses for out-of-sample residuals. Must be provided together with newx. If NULL (default), training residuals are returned.
...	not used, only here for S3 compatibility

**Value**

Matrix of residuals, each column corresponding to a value of `lambda1`.

---

ridge	<i>Fit a linear model with a structured ridge regularization</i>
-------	--

---

**Description**

Adjust a linear model with ridge regularization (possibly structured  $\ell_2$ -norm). The solution path is computed at a grid of values for the  $\ell_2$ -penalty. See details for the criterion optimized.

**Usage**

```
ridge(
  x,
  y,
  lambda = NULL,
  weights = rep(1, nrow(x)),
  struct = Matrix::Diagonal(ncol(x), 1),
  penscale = rep(1, ncol(x)),
  intercept = TRUE,
  normalize = TRUE,
  nlambdas = 100,
  minratio = 1e-05,
  lambda_max = 100,
  control = list()
)
```

**Arguments**

x	matrix of features, possibly sparsely encoded (experimental). Do NOT include intercept. When normalized is TRUE, coefficients will then be rescaled to the original scale.
y	response vector.
lambda	sequence of decreasing $\ell_2$ -penalty levels. If NULL (the default), a vector is generated with <code>nlambdas</code> entries, starting from a guessed level <code>lambda_max</code> where only the intercept is included, then shrunk to <code>minratio*lambda_max</code> .
weights	vector with real positive values that weight the observations (like in weighted least square). Default sets all weights to 1.
struct	matrix structuring the coefficients, possibly sparsely encoded. Must be at least positive semidefinite (this is checked internally). If NULL (the default), the identity matrix is used. See details below.

<code>penscale</code>	vector with real positive values that weight the penalty of each feature. Default sets all weights to 1.
<code>intercept</code>	logical; indicates if an intercept should be included in the model. Default is TRUE.
<code>normalize</code>	logical; indicates if variables should be normalized to have unit L2 norm before fitting. Default is TRUE.
<code>nlambda</code>	integer that indicates the number of values to put in the <code>lambda</code> vector. Ignored if <code>lambda</code> is provided.
<code>minratio</code>	minimal value of $\ell_1$ -part of the penalty that will be tried, as a fraction of the maximal <code>lambda1</code> value. A too small value might lead to instability at the end of the solution path corresponding to small <code>lambda1</code> combined with $\lambda_2 = 0$ . The default value tries to avoid this, adapting to the ' $n < p$ ' context. Ignored if <code>lambda1</code> is provided.
<code>lambda_max</code>	the largest value of <code>lambda</code> considered
<code>control</code>	list of argument controlling low level options of the algorithm –use with care and at your own risk– : <ul style="list-style-type: none"> <li>• <code>verbose</code>: integer; activate verbose mode –this one is not too risky!– set to 0 for no output; 1 for warnings only, and 2 for tracing the whole progression. Default is 1. Automatically set to 0 when the method is embedded within cross-validation or stability selection.</li> <li>• <code>timer</code>: logical; use to record the timing of the algorithm. Default is FALSE.</li> <li>• <code>maxiter</code> the maximal number of iteration used in the active set algorithm to solve the problem for a given value of <code>lambda1</code> . Default is 50.</li> <li>• <code>method</code> a string for the underlying solver used. Either "quadra", "fista" or "pgd". Default is "quadra".</li> <li>• <code>factmat</code> Boolean indicating if matrix factorization should be used to solve the sub-system. If TRUE (the default), a Cholesky decomposition is maintained along the path. If FALSE, the sub-system are solved with a conjugate gradient algorithm.</li> <li>• <code>threshold</code> a threshold for convergence. The algorithm stops when the optimality conditions are fulfill up to this threshold. Default is 1e-6.</li> <li>• <code>monitor</code> indicates if a monitoring of the convergence should be recorded, by computing a lower bound between the current solution and the optimum: when '0' (the default), no monitoring is provided; when '1', the bound derived in Grandvalet et al. is computed; when '&gt;1', the Fenchel duality gap is computed along the algorithm.</li> </ul>

## Details

The optimized criterion is the following:

$$\hat{\beta}_{\lambda_2} = \arg \min_{\beta} \frac{1}{2} (y - X\beta)^T (y - X\beta) + \frac{\lambda_2}{2} \beta^T S \beta,$$

where the  $\ell_2$  structuring positive semidefinite matrix  $S$  is provided via the `struct` argument (possibly of class `Matrix`).

**Value**

an object with class [RidgeRegressionFit](#), inheriting from [QuadrupenFit](#).

**See Also**

See also [QuadrupenFit](#)

**Examples**

```
## Simulating multivariate Gaussian with blockwise correlation
## and piecewise constant vector of parameters
beta <- rep(c(0,1,0,-1,0), c(25,10,25,10,25))
cor <- 0.75
Soo <- toeplitz(cor^(0:(25-1))) ## Toeplitz correlation for irrelevant variables
Sww <- matrix(cor,10,10) ## bloc correlation between active variables
Sigma <- Matrix::bdiag(Soo,Sww,Soo,Sww,Soo)
diag(Sigma) <- 1
n <- 50
x <- as.matrix(matrix(rnorm(95*n),n,95) %%% chol(Sigma))
y <- 10 + x %%% beta + rnorm(n,0,10)

labels <- rep("irrelevant", length(beta))
labels[beta != 0] <- "relevant"
plot(ridge(x,y) , label=labels) ## a mess
plot(ridge(x,y, struct=solve(Sigma)), label=labels) ## even better
```

---

RidgeRegressionFit      *Class "RidgeRegressionFit"*

---

**Description**

Class of object returned by the fitting function [ridge\(\)](#). Inherits fields and methods of [QuadrupenFit](#).

**Super class**

[QuadrupenFit](#) -> RidgeRegressionFit

**Active bindings**

penalty character describing the regularizer/penalty  
lambda2 vector of tuning parameters for the l2 penalty

**Methods****Public methods:**

- [RidgeRegressionFit\\$new\(\)](#)
- [RidgeRegressionFit\\$clone\(\)](#)

[RidgeRegressionFit\\$new\(\)](#): Initialize a [RidgeRegressionFit](#) model

*Usage:*

```
RidgeRegressionFit$new(data, intercept, regParam)
```

*Arguments:*

data a [DataModel](#) object

intercept a logical; should an intercept be included in the mode?

regParam a list with two elements, a vector and a scalar, for the regularization

[RidgeRegressionFit\\$clone\(\)](#): The objects of this class are cloneable with this method.

*Usage:*

```
RidgeRegressionFit$clone(deep = FALSE)
```

*Arguments:*

deep Whether to make a deep clone.

**See Also**

[QuadrupenFit](#), [ridge\(\)](#)

---

selection

*Variable selection from a stability path*

---

**Description**

S3 generic for variable selection based on a [StabilityPath](#) object, as introduced by Meinshausen and Bühlmann (2010).

**Usage**

```
selection(object, ...)
```

```
## S3 method for class 'StabilityPath'
selection(
  object,
  sel_mode = c("rank", "PFER"),
  cutoff = 0.75,
  PFER = 2,
  nvarsel = NULL,
  ...
)
```

**Arguments**

object	a <a href="#">StabilityPath</a> object.
...	not used, only here for S3 compatibility.
sel_mode	a character string, either "rank" or "PFER". Default is "rank".
cutoff	probability threshold for sel_mode = "PFER". Default is 0.75.
PFER	per-family error rate to control for sel_mode = "PFER". Default is 2.
nvarsel	number of variables to select for sel_mode = "rank". Default is $\text{floor}(\text{nobs} / \log(\text{nvar}))$ .

**Value**

an integer vector of selected variable indices.

**Methods (by class)**

- `selection(StabilityPath)`: S3 method for variable selection from a [StabilityPath](#)

SparseFit

*Class "SparseFit"*

---

**Description**

Class of object returned by the fitting function [elastic\\_net\(\)](#). Inherits fields and methods of [QuadrupenFit](#)

**Super class**

[QuadrupenFit](#) -> SparseFit

**Active bindings**

lambda1 vector of tuning parameters for the l1 penalty  
 lambda2 vector of tuning parameters for the l2 penalty  
 penalty character describing the regularizer/penalty  
 type string the type of group-wise regularization applied  
 unbiasing\_tuning unbiasing coefficient of the MCP or SCAD penalties

**Methods****Public methods:**

- [SparseFit\\$new\(\)](#)
- [SparseFit\\$clone\(\)](#)

[SparseFit\\$new\(\)](#): Initialize a [SparseFit](#) model

*Usage:*

```
SparseFit$new(data, intercept, type, regParam)
```

*Arguments:*

data a [DataModel](#) object

intercept a logical; should an intercept be included in the mode?

type string the type of group-wise regularization applied

regParam a list with two elements, a vector and a scalar, for the regularization

[SparseFit\\$clone\(\)](#): The objects of this class are cloneable with this method.

*Usage:*

```
SparseFit$clone(deep = FALSE)
```

*Arguments:*

deep Whether to make a deep clone.

SparseGroupFit	Class " <i>SparseGroupFit</i> "
----------------	---------------------------------

---

**Description**

Class of object returned by the fitting function [group\\_sparse\\_lm\(\)](#). Inherits fields and methods of [QuadrupenFit](#)

**Super class**

[QuadrupenFit](#) -> SparseGroupFit

**Active bindings**

lambda1 vector of tuning parameters for the l1 group penalty

lambda2 vector of tuning parameters for the l2 penalty

alpha mixing parameter of the sparse group-penalty

penalty character describing the regularizer/penalty

group vector of integers indicating group belonging

type string the type of group-wise regularization applied

mixture\_tuning mixture coefficient of the sparse group penalty

is\_group\_sparse boolean indicating if sparse group or group penalty is applied

**Methods****Public methods:**

- [SparseGroupFit\\$new\(\)](#)
- [SparseGroupFit\\$clone\(\)](#)

[SparseGroupFit\\$new\(\)](#): Initialize a [SparseGroupFit](#) model

*Usage:*

```
SparseGroupFit$new(data, intercept, group, type, regParam)
```

*Arguments:*

data a [DataModel](#) object

intercept a logical; should an intercept be included in the mode?

group vector of integers indicating group belonging.

type string indicating whether the  $\ell_1/\ell_2$  or the  $\ell_1/\ell_\infty$  group-Lasso must be fitted.

regParam a list with two elements, a vector and a scalar, for the regularization

[SparseGroupFit\\$clone\(\)](#): The objects of this class are cloneable with this method.

*Usage:*

```
SparseGroupFit$clone(deep = FALSE)
```

*Arguments:*

deep Whether to make a deep clone.

**See Also**

[QuadrupenFit](#), [group\\_sparse\\_lm\(\)](#)

sparse\_lm

*Fit a linear model with sparse regularization*

---

**Description**

Adjust a linear model with sparse regularization. We also add a (possibly structured)  $\ell_2$ -norm (ridge-like). The solution path is computed at a grid of values for the  $\ell_1$ -penalty, fixing the amount of  $\ell_2$  regularization. See details for the criterion optimized.

**Usage**

```
sparse_lm(
  x,
  y,
  type = c("l1", "mcp", "scad"),
  lambda1 = NULL,
  lambda2 = 0.01,
  eta = 3.7,
  weights = rep(1, nrow(x)),
```

```

penscale = rep(1, ncol(x)),
struct = Matrix::Diagonal(ncol(x), 1),
intercept = TRUE,
normalize = TRUE,
refit = FALSE,
nlambda1 = ifelse(is.null(lambda1), 100, length(lambda1)),
minratio = ifelse(nrow(x) <= ncol(x), 0.01, 1e-04),
maxfeat = ifelse(lambda2 < 0.01, min(nrow(x), ncol(x)), min(4 * nrow(x), ncol(x))),
beta0 = numeric(ncol(x)),
control = list()
)

elastic.net(
  x,
  y,
  lambda1 = NULL,
  lambda2 = 0.5,
  weights = rep(1, nrow(x)),
  penscale = rep(1, ncol(x)),
  struct = Matrix::Diagonal(ncol(x), 1),
  intercept = TRUE,
  normalize = TRUE,
  refit = FALSE,
  nlambda1 = ifelse(is.null(lambda1), 100, length(lambda1)),
  minratio = ifelse(nrow(x) <= ncol(x), 0.01, 1e-04),
  maxfeat = ifelse(lambda2 < 0.01, min(nrow(x), ncol(x)), min(4 * nrow(x), ncol(x))),
  beta0 = numeric(ncol(x)),
  control = list(method = "quadra")
)

elastic_net(

  nlambda1 = ifelse(is.null(lambda1), 100, length(lambda1)),
```

```

minratio = ifelse(nrow(x) <= ncol(x), 0.01, 1e-04),
maxfeat = ifelse(lambda2 < 0.01, min(nrow(x), ncol(x)), min(4 * nrow(x), ncol(x))),
beta0 = numeric(ncol(x)),
control = list(method = "quadra")
)

```

### Arguments

<code>x</code>	matrix of features, possibly sparsely encoded (experimental). Do NOT include intercept. When normalized is TRUE, coefficients will then be rescaled to the original scale.
<code>y</code>	response vector.
<code>type</code>	string indicating the sparse variant to be fitted. Could be "l1", "mcp" or "scad". Default is "l1". be careful as scad and mcp are still experimental and have not been fully tested yet
<code>lambda1</code>	sequence of decreasing $\ell_1$ -penalty levels. If NULL (the default), a vector is generated with <code>nlambda1</code> entries, starting from a guessed level <code>lambda1.max</code> where only the intercept is included, then shrunken to <code>minratio*lambda1.max</code> .
<code>lambda2</code>	real scalar; tunes the $\ell_2$ penalty in the Elastic-net. Default is 0.01. Set to 0 to recover the Lasso.
<code>eta</code>	real positive scalar for tuning SCAD or MCP penalties. Default is 3.7. Ignored when <code>type == "l1"</code> .
<code>weights</code>	vector with real positive values that weight the observations (like in weighted least square). Default sets all weights to 1.
<code>penscale</code>	vector with real positive values that weight the penalty of each feature. Default sets all weights to 1.
<code>struct</code>	matrix structuring the coefficients, possibly sparsely encoded. Must be at least positive semidefinite (this is checked internally). If NULL (the default), the identity matrix is used. See details below.
<code>intercept</code>	logical; indicates if an intercept should be included in the model. Default is TRUE.
<code>normalize</code>	logical; indicates if variables should be normalized to have unit L2 norm before fitting. Default is TRUE.
<code>refit</code>	logical: indicates if the non null coefficients should be refit to avoid excessive bias. Default is FALSE. Can be changed later (both raw and refit coefficients are stored).
<code>nlambda1</code>	integer that indicates the number of values to put in the <code>lambda1</code> vector. Ignored if <code>lambda1</code> is provided.
<code>minratio</code>	minimal value of $\ell_1$ -part of the penalty that will be tried, as a fraction of the maximal <code>lambda1</code> value. A too small value might lead to instability at the end of the solution path corresponding to small <code>lambda1</code> combined with $\lambda_2 = 0$ . The default value tries to avoid this, adapting to the ' $n < p$ ' context. Ignored if <code>lambda1</code> is provided.

maxfeat	integer; limits the number of features ever to enter the model; i.e., non-zero coefficients for the Elastic-net: the algorithm stops if this number is exceeded and lambda1 is cut at the corresponding level. Default is $\min(\text{nrow}(x), \text{ncol}(x))$ for small lambda2 ( $<0.01$ ) and $\min(4*\text{nrow}(x), \text{ncol}(x))$ otherwise. Use with care, as it considerably changes the computation time.
beta0	a starting point for the vector of parameter. By default, will initialized zero. May save time in some situation.
control	list of argument controlling low level options of the algorithm –use with care and at your own risk– : <ul style="list-style-type: none"> <li>• verbose: integer; activate verbose mode –this one is not too risky!– set to 0 for no output; 1 for warnings only, and 2 for tracing the whole progression. Default is 1. Automatically set to 0 when the method is embedded within cross-validation or stability selection.</li> <li>• timer: logical; use to record the timing of the algorithm. Default is FALSE.</li> <li>• maxiter the maximal number of iteration used in the active set algorithm to solve the problem for a given value of lambda1 . Default is 50.</li> <li>• method a string for the underlying solver used. Either "quadra", "fista" or "pgd". Default is "quadra".</li> <li>• factmat Boolean indicating if matrix factorization should be used to solve the sub-system. If TRUE (the default), a Cholesky decomposition is maintained along the path. If FALSE, the sub-system are solved with a conjugate gradient algorithm.</li> <li>• threshold a threshold for convergence. The algorithm stops when the optimality conditions are fulfill up to this threshold. Default is <math>1e-6</math>.</li> <li>• monitor indicates if a monitoring of the convergence should be recorded, by computing a lower bound between the current solution and the optimum: when '0' (the default), no monitoring is provided; when '1', the bound derived in Grandvalet et al. is computed; when '&gt;1', the Fenchel duality gap is computed along the algorithm.</li> </ul>

## Details

The optimized criterion is the following:

$$\hat{\beta}_{\lambda_1, \lambda_2} = \arg \min_{\beta} \frac{1}{2} (y - X\beta)^T (y - X\beta) + \lambda_1 \text{pen}_{\eta}(D\beta) + \frac{\lambda_2}{2} \beta^T S \beta,$$

where  $D$  is a diagonal matrix, whose diagonal terms are provided as a vector by the penscale argument. The  $\ell_2$  structuring matrix  $S$  is provided via the struct argument, a positive semidefinite matrix (possibly of class Matrix).

## Value

an object with class [SparseFit](#), inheriting from [QuadrupenFit](#).

```

---

stability

*Stability selection for Quadrupen object*

---

**Description**

Compute the stability path of a (possibly randomized) fitting procedure as introduced by Meinshausen and Bühlmann (2010).

**Usage**

```

stability(
  object,

```

```

    n_subsamples = 50,
    subsample_size = floor(object$nobs/2),
    subsamples = replicate(n_subsamples, sample(1:object$nobs, subsample_size), simplify =
      FALSE),
    weakness = 1,
    verbose = TRUE,
    cores = 1
  )

## S3 method for class 'QuadrupenFit'
stability(
  object,
  n_subsamples = 50,
  subsample_size = floor(object$nobs/2),
  subsamples = replicate(n_subsamples, sample(1:object$nobs, subsample_size), simplify =
    FALSE),
  weakness = 1,
  verbose = TRUE,
  cores = parallel::detectCores() - 2
)

```

### Arguments

<code>object</code>	an R6 object with class <a href="#">QuadrupenFit</a>
<code>n_subsamples</code>	integer indicating the number of subsamplings used to estimate the selection probabilities. Default is 100.
<code>subsample_size</code>	integer indicating the size of each subsamples. Default is <code>floor(n/2)</code> .
<code>subsamples</code>	list with <code>subsamples</code> entries with vectors describing the folds to use for the stability procedure. By default, the folds are randomly sampled with the specified <code>n_subsamples</code> and <code>subsample_size</code> argument.
<code>weakness</code>	Coefficient used for randomizing the weights of each features. Default is 1* for no randomization. See details below.
<code>verbose</code>	logical; indicates if the progression should be displayed. Default is TRUE.
<code>cores</code>	the number of cores to use. The default uses 1 core (safer in case your BLAS/LAPACK libraries are multithreaded)

### Value

an object with class [StabilityPath](#) is sent back and stored as a field of the original [QuadrupenFit](#) object.

### Methods (by class)

- `stability(QuadrupenFit)`: S3 method for stability selection of a [QuadrupenFit](#)

**Note**

When  $\text{weakness} < 1$ , the `penscale` argument that weights the penalty tuned by  $\lambda_1$  is perturbed (divided) for each subsample by a random variable uniformly distributed on  $[\alpha, 1]$ , where  $\alpha$  is the weakness parameter.

If the user runs the fitting method with option `'bulletproof'` set to `FALSE`, the algorithm may stop at an early stage of the path. Early stops of the underlying fitting function are handled internally, in the following way: we chose to simply skip the results associated with such runs, in order not to bias the stability selection procedure. If it occurs too often, a warning is sent to the user, in which case you should reconsider the grid of `lambda1` for stability selection. If `bulletproof` is `TRUE` (the default), there is nothing to worry about, except a possible slow down when any switching to the proximal algorithm is required.

stab <- stability(enet, n_subsamples = 200)

## Build the plot and recover the selected variable
plot(stab, labels=labels)
stabpath <- plot(stab, xvar="fraction", labels=labels, sel_mode="PFER", cutoff=0.75, PFER=1)

cat("\nFalse positives for the randomized Elastic-net with stability selection: ",
    sum(labels[stab$selection()] != "relevant"))
cat("\nDONE.\n")

## End(Not run)
```

---

StabilityPath	<i>Class StabilityPath</i>
---------------	----------------------------

---

### Description

Class of object returned by the `QuadrupenFit$cross_validate()` method or the `cross_validate()` function. Owns `print()` and `plot()` methods.

### Public fields

`probabilities` a Matrix object containing the estimated probabilities of selection along the path of solutions.

`regParam` a list with the levels of the regularizing parameters used

`subsamples` a list that contains the folds used for each subsample.

### Active bindings

`nvar` number of variables (without intercept)

`nobs` number of observation/sample size

`nonzero` variables with a non-null probability of selection along the stability path

`nonzeroprob` subset of the probabilities stability path on the nonzero variables

### Methods

#### Public methods:

- `StabilityPath$new()`
- `StabilityPath$show()`
- `StabilityPath$print()`
- `StabilityPath$selection()`
- `StabilityPath$plot()`
- `StabilityPath$clone()`

`StabilityPath$new()`: Constructor for a `StabilityPath` object Should be called internally by an object `QuadrupenFit$stability()`

*Usage:*

`StabilityPath$new(probabilities, regParam, subsamples)`

*Arguments:*

`probabilities` a Matrix object containing the estimated probabilities of selection along the path of solutions.

`regParam` a list with the levels of the regularizing parameters used

`subsamples` a list that contains the folds used for each subsample.

`StabilityPath$show()`: User friendly print method

*Usage:*

```
StabilityPath$show()
```

StabilityPath\$print(): User friendly print method

*Usage:*

```
StabilityPath$print()
```

StabilityPath\$selection(): Perform variable selection based on the stability path

*Usage:*

```
StabilityPath$selection(
  sel_mode = c("rank", "PFER"),
  cutoff = 0.75,
  PFER = 2,
  nvarsel = floor(self$nobs/log(self$nvar))
)
```

*Arguments:*

`sel_mode` a character string, either "rank" or "PFER". In the first case, the selection is based on the rank of total probabilities by variables along the path: the first `nvarsel` variables are selected (see below). In the second case, the PFER control is used as described in Meinshausen and Bühlmann's paper. Default is "rank".

`cutoff` value of the cutoff probability (only relevant when `sel_mode` equals "PFER").

`PFER` value of the per-family error rate to control (only relevant when `sel_mode` equals "PFER").

`nvarsel` number of variables selected (only relevant when `sel_mode` equals "rank". Default is  $\text{floor}(n/\log(p))$ ).

StabilityPath\$plot(): Produce a plot of the stability path obtained by stability selection.

*Usage:*

```
StabilityPath$plot(
  xvar = "lambda",
  title = "Stability path",
  labels = rep("unknown status", self$nvar),
  sel_mode = c("rank", "PFER"),
  cutoff = 0.75,
  PFER = 2,
  nvarsel = min(self$nvar, floor(self$nobs/log(self$nvar)))
)
```

*Arguments:*

`xvar` variable to plot on the X-axis: either "lambda" (first penalty level) or "fraction" (fraction of the penalty level applied tune by  $\lambda_1$ ). Default is "lambda".

`title` title title. If none given, a somewhat appropriate title is automatically generated.

`labels` an optional vector of labels for each variable in the path (e.g., 'relevant'/'irrelevant'). See examples.

`sel_mode` a character string, either "rank" or "PFER". In the first case, the selection is based on the rank of total probabilities by variables along the path: the first `nvarsel` variables are selected (see below). In the second case, the PFER control is used as described in Meinshausen and Bühlmann's paper. Default is "rank".

cutoff value of the cutoff probability (only relevant when sel\_mode equals "PFER").  
 PFER value of the per-family error rate to control (only relevant when sel\_mode equals "PFER").  
 nvarsel number of variables selected (only relevant when sel\_mode equals "rank". Default is floor(n/log(p)).  
 plot logical; indicates if the graph should be plotted. Default is TRUE. If FALSE, only the **ggplot2** object is sent back.

*Returns:* a list with a **ggplot2** object which can be plotted via the print method, and a vector of selected variables corresponding to method of choice ("rank" or "PFER").

*Examples:*

```
## Simulating multivariate Gaussian with blockwise correlation
## and piecewise constant vector of parameters
beta <- rep(c(0,1,0,-1,0), c(25,10,25,10,25))
Soo <- matrix(0.75,25,25) ## bloc correlation between zero variables
Sww <- matrix(0.75,10,10) ## bloc correlation between active variables
Sigma <- Matrix::bdiag(Soo,Sww,Soo,Sww,Soo) + 0.2
diag(Sigma) <- 1
n <- 100
x <- as.matrix(matrix(rnorm(95*n),n,95) %%% chol(Sigma))
y <- 10 + x %%% beta + rnorm(n,0,10)

## Build a vector of label for true nonzeros
labels <- rep("irrelevant", length(beta))
labels[beta != 0] <- c("relevant")
labels <- factor(labels, ordered=TRUE, levels=c("relevant","irrelevant"))

enet <- elastic_net(x, y, lambda2 = 10, struct = solve(Sigma), minratio = 1e-2)
stab <- stability(enet, n_subsamples = 200)

## Build the plot and recover the selected variable
plot(stab, labels=labels)

cat("\nFalse positives for the randomized Elastic-net with stability selection: ",
    sum(labels[stab$selection()] != "relevant"))
cat("\nDONE.\n")
```

StabilityPath\$clone(): The objects of this class are cloneable with this method.

*Usage:*

```
StabilityPath$clone(deep = FALSE)
```

*Arguments:*

deep Whether to make a deep clone.

## Examples

```
## -----
## Method `StabilityPath$plot()`
## -----
```

```
## Not run:
## Simulating multivariate Gaussian with blockwise correlation
## and piecewise constant vector of parameters
